

Assignment3: Recurrent Neural Networks

Koç University COMP441-541

Due on December 14th Sunday, 2025 (23:59:59)

Introduction

Goals

The primary goal with this assignment is to give you hands-on experience implementing a neural network language model using recurrent neural networks. Understanding how these neural models work and building one from scratch will help you understand not just language modeling, but also systems for many other applications such as machine translation. Please use Python 3.5+ and PyTorch 1.0+ for this project.

Data

The dataset for this paper is the text8 (<http://mattmahoney.net/dc>) collection. This is a dataset taken from the first 100M characters of Wikipedia. Only 27 character types are present (lowercase characters and spaces); special characters are replaced by a single space and numbers are spelled out as individual digits (20 becomes two zero). A larger version of this benchmark (90M training characters, 5M dev, 5M test) was used in Mikolov et al. (2012).

Part1: RNNs for Classification (40 points)

In this first part, you will do a simplified version of the language modeling task: binary classification of fixed-length sequences to predict whether the given sequence is followed by a consonant or a vowel. You will implement the entire training and evaluation loop for this model.

Data

train-vowel-examples.txt and *train-consonant-examples.txt* each contain 5000 strings of length 20, and *dev-vowel-examples.txt* and *dev-consonant-examples.txt* each contain 500. The task is to predict whether the first letter following each string is a vowel or a consonant. The consonant file (for both train and test) contains examples where the next letter (in the original text, not shown) was a consonant, and analogously for the vowel file.

Getting started

Run: `python lm_classifier.py`. This loads the data for this part, learns a `FrequencyBasedClassifier` on the data, and evaluates it. This classifier gets 71.4% accuracy, where random guessing gets you 50%. `lm_classifier.py` contains the driver code, and the top of `models.py` contains the skeletal implementation for this classifier.

```

Q1 (40 points)

Implement an RNN classifier to classify segments as being followed by consonants or vowels. This will require defining a PyTorch module to do this classification, implementing training of that module in `train_rnn_classifier`, and finally completing the definition of `RNNClassifier` appropriately to use this module for classification. You can find the skeleton codes for `RNNClassifier` and `train_rnn_classifier` in the below cells.

Important Note: Your final model should get at least 75% accuracy. In your report, you should: (1) Describe your model and implementation. (2) Report accuracy results and timing information. Even if you are not able to get this part fully working, write up and document as much as you can so we can give appropriate partial credit.

Network Structure

The inputs to your network will be sequences of character indices. You should first embed these using a `nn.Embedding` layer and then feed the resulting tensor into an RNN. Two effective types of RNNs to use are `nn.GRU` and `nn.LSTM`. Their weights

should be randomly initialized when you construct them, though you are also free to experiment with different initializers such as the Glorot initializer (`nn.init.xavier_uniform`). You should take the output of the RNN (the last hidden state) and use it for binary classification with a softmax layer. You can add one or more feedforward layers before the softmax layer if you want. You can make your own `nn.Module` that wraps the embedding layer, RNN, and classification layer.

Code Structure

Once you have your own module implemented, the training and eval loop that wraps them will look roughly the same as in previous assignments. First, you need a function to go from the raw string to a PyTorch tensor of indices. Then loop through those examples, zero your gradients, pick up an example, compute the loss, run backpropagation, and update parameters with your optimizer. You should implement this training in `train_rnn_classifier`.

Using RNNs

LSTMs and GRUs can be a bit trickier to use than feedforward architectures. First, these expect input tensors of dimension [sequence length, batch size, input size]. You can use the `batch first` argument to switch whether the sequence length dimension or batch dimension occurs first. If you're not using batching, you'll want to pad your sentence with a trivial 1 dimension for the batch. `unsqueeze` allows you to add trivial dimensions of size 1, and `squeeze` lets you remove these. Second, an LSTM takes as input a pair of tensors representing the state, `h` and `c`. Each is of size [num layers * num directions, batch size, hidden size]. To start with, you probably want a 1-layer RNN just running in the forward direction, so once again you should use `unsqueeze` to make a 3-tensor with first dimension length of 1. GRUs are similar but only have one hidden state.

Tensor Manipulation

`np.asarray` can convert lists into numpy arrays easily. `torch.from_numpy` can convert numpy arrays into PyTorch tensors. `torch.FloatTensor(list)` can convert from lists directly to PyTorch tensors. `.float()` and `.int()` can be used to cast tensors to different types.

General Tips

As always, make sure you can overfit a very small training set as an initial test. If not, you probably have a bug. Then scale up to train on more data and check the development performance of your model. Consider using small values for hyperparameters so things train quickly. In particular, with only 27 characters, you can get away with small embedding sizes for these, and small hidden sizes for the RNN may work better than you think!

Model:

I implemented an RNN classifier to predict the next character is consonant or vowel given a sequence. In my architecture I have:

1. Embedding layer: Maps the 27 characters to a 64-dimensional vector
2. RNN layer: Either LSTM or GRU
3. Fully connected layer: Classifies the last hidden state as consonant or vowel
4. Loss function: I used cross entropy loss

Hyperparameters:

I tried various hyperparameters but I got the +75% accuracy using these hyperparameters:

- Embedding dimension: 64
- Hidden dimension: 128
- Batch size: 128
- Learning rate: 0.001
- Weight decay: 1e-4
- Number of epochs: 10

Results:

Model	Train Accuracy	Dev Accuracy	Training Time
LSTM	83.65%	77.00%	8.38s
GRU	83.24%	76.70%	7.13s

- Both models exceeded the required accuracy (75%). GRU trained faster than LSTM, it might be because GRU has fewer gates and because of that GRU has fewer parameters so it trains faster. LSTM achieved higher accuracy on dev set but the difference between two models are really close.

Part 2: Implementing a Language Model (60 points)

In this second part, you will implement an RNN language model. This should build heavily off of what you did for Part 1, though new ingredients will be necessary, particularly during training.

Data

For this part, we use the first 100,000 characters of text8 as the training set. The development set is 500 characters taken from elsewhere in the collection.

Getting started

Run the below cell. This loads the data, instantiates a UniformLanguageModel which assigns each character an equal $1/27$ probability, and evaluates it on the development set. This model achieves a total log probability of -1644, an average log probability (per token) of -3.296, and a perplexity of 27. Note that exponentiating the average log probability gives you $1/27$ in this case, which is the inverse of perplexity. The RNNLanguageModel class you are given has two methods: get_next_char_log_probs and get_log_prob_sequence. The first takes a context and returns the log probability distribution over the next characters given that context as a numpy vector of length equal to the vocabulary size. The second takes a whole sequence of characters and a context and returns the log probability of that whole sequence under the model. You can implement the second just using the first, but that's computationally wasteful; you can instead just run a single pass through the RNN and return the aggregated log probability of the sequence.

```
In [285... class LanguageModel(object):

    def get_next_char_log_probs(self, context) -> np.ndarray:
        """
        Returns a log probability distribution over the next characters g
        The log should be base e
        :param context: a single character to score
        :return: A numpy vector log P(y | context) where y ranges over th
        """
        raise Exception("Only implemented in subclasses")

    def get_log_prob_sequence(self, next_chars, context) -> float:
        """
        Scores a bunch of characters following context. That is, returns
        log P(nc1, nc2, nc3, ... | context) = log P(nc1 | context) + log
        The log should be base e
        :param next_chars:
        :param context:
        :return: The float probability
        """

Q2 (60 points)

Implement an RNN language model. This will require: defining a PyTorch module to handle language model prediction, implementing training of that module in `train_lm` function, and finally completing the definition of `RNNLanguageModel` appropriately to use this module for prediction. Skeleton codes for `train_lm` and `RNNLanguageModel` are provided to you in the cells below. Your network should take indexed characters as input, embed them, put them through an RNN, and make predictions from the final layer outputs.

Your final model must pass the sanity and normalization checks, get a perplexity value less than or equal to 7. In your report, you should: (1) Describe your model and implementation. (2) Report accuracy results and any relevant time information. As with Part 1, even if you are not able to get this part fully working, write up and document as much as you can so we can give appropriate partial credit.

Chunking the Data

Unlike classification, language modeling can be viewed as a task where the same network is predicting words at many positions. Your network should process a chunk

of characters at a time, simultaneously predicting the next character at each index in the chunk. You'll have to decide how you want to chunk the data. Given a chunk, you can either initialize the RNN state with a zero vector, "burn in" the RNN by running on a few characters before you begin predicting, or carry over the end state of the RNN to the next state. These may only make minor differences, though.

Start of Sequence

In general, the beginning of any sequence is represented to the language model by a special start-of-sequence token. This means that the inputs and outputs of a language model are slightly different, since an LM will never output the start-of-sequence character but may need to read it as input. For simplicity, we are going to overload space and use that as the start-of-sequence character.

Evaluation

In that part, your model is evaluated on perplexity and likelihood, which rely on the probabilities that your model returns. Your model should be a correct implementation of a language model. That is, it should be a probability distribution $P(w_i | w_1, \dots, w_{i-1})$. You should be sure to check that your model's output is indeed a legal probability distribution over the next word.

Batching

Batching across multiple sequences can further increase the speed of training. While you do not need to do this to complete the assignment, you may find the speedups helpful. As in Assignment 2, you should be able to do this by increasing the dimension of your tensors by 1, a batch dimension which should be the first dimension of each tensor. The rest of your code should be largely unchanged. Note that you only need to apply batching during training, as the two inference methods you'll implement aren't set up to pass you batched data anyway.

Model:

I implemented a RNN language model to predict the next character by looking at the previous characters. My model architecture has:

1. Embedding layer: Maps each of the 27 characters to a 64-dimensional vector
2. RNN layer: Either LSTM or GRU
3. Fully connected layer: Used to predict the next character
4. Loss function: NLLLoss

Hyperparameters:

I trained both LSTM and GRU with different hyperparameters but I got the best results with:

- Embedding dimension: 64
- Hidden dimension: 128
- Sequence length: 50 characters per chunk
- Batch size: 64
- Learning rate: 0.001
- Weight decay: 1e-4
- Number of epochs: 10

Sequence Length:

- I tried different numbers of chunks sizes (60, 55, 52, 50), results are like this:
 - When sequence length was 60 both types of RNNs got the highest perplexity (LSTM's perplexity = 6.60, GRU's perplexity = 6.13), when I lowered the sequence length the perplexity values dropped. The best perplexity and other results are achieved using 50 for the sequence length.

Chunking Strategy:

- I split both the training and dev text into fixed sized chunks which has 50 characters each. For the input chunk, it stores characters from [0:49] (doesn't store the character) and the target chunk stores characters from [1:50]. This allows model to predict the next character.

Results:

Model	Dev Accuracy	Total Training Time	Total Log Prob	Avg Log Prob	Perplexity
LSTM	45.33%	~5.2s	-914.36	-1.8287	6.18
GRU	46.22%	~4.9s	-858.28	-1.7166	5.67

- Both models met the required perplexity threshold(< 7).
- Both models passed the sanity and normalization checks
- GRU achieved better perplexity and higher average log probability compared to the LSTM, this means that GRU had a better predictive performance and also computationally more efficient than LSTMs
- Models accuracy is not that high but since we are evaluating the models for perplexity and likelihood, accuracies won't matter too much.

Part 3 (Bonus 20 pts): Needle in a Haystack Problem

Now, we introduce a recent problem known as the Needle in a Haystack Problem.

Here, we will take a dataset, and at random positions in each input, we will insert text of the form **Passcode: N** where N is a random digit from **0** to **9**. The goal of the problem is to give the entire input to the model, and have the model output what the passcode digit is.

For example, if the original input is **First, you know Caius Marcius is chief enemy to the people.**, we might process this to be **First, you know Caius Marcius Passcode: 5 is chief enemy to the people.**, and want the model to classify this text as **5**. Wherever this passcode is added, make sure to put spaces before and after.

We will use the shakespeare dataset introduced in Tutorial 6.

Step 1: Prepare the Dataset and Processor

You will need to load the dataset. To do so, you can adapt the code provided in Tutorial 6. However, you will need to write a function called `add_passcode(text)` which adds a random passcode to the text. For this function, make sure to return both the text with the passcode added, as well as the passcode itself (You will need this as a label for training). After this, you will also need to be able to convert the text into ids.

Step 2: Setup and Train the Model

To train a model on this task, you can adapt the classification model from Part 1. It will need to predict 10 classes corresponding to the 10 digits. Experiment with a vanilla RNN, LSTM, and GRU, as well as different settings, and determine what the best performance you can get on this task is. Report all of these results for different architectures and training setups.

**** This is a challenging task, do not expect to be able to get high results with a small dataset and small model ****

Models and Results:

- My initial models were:

1. Vanilla Rnn
2. LSTM RNN
3. GRU RNN

- Initially I tried to train all the models with the whole dataset but because the dataset was too big for my computer, training was taking too long and I decided to use 5000 examples for training set and 1000 examples for the dev set. I initially trained the models with these hyperparameters:

- embedding_dim = 32
- hidden_dim = 64
- output_dim = 10
- batch_size = 128
- num_epochs = 15
- learning_rate = 0.001
- optimizer: Adam optimizer

- Initially I did not use weight decay because when I added weight decay the accuracies dropped down significantly but after removing weight decay GRU got 100% accuracy on the dev set so I decided to add the weight decay again. The best results I got with hyperparameters above + weight decay = $1e-4$ is like this:

Model	Dev Accuracy
RNN	10.60%
LSTM	53.40%
GRU	53.20%

- LSTM and GRU significantly outperformed vanilla RNN, achieved nearly 5 times better accuracy than vanilla RNN.
- Vanilla RNN might not have a good performance because of the vanishing gradient problem and also the low accuracy might be because, I padded the sentences in the batches so that they have the same length. The more I padded

the more time vanilla RNN spends time to understand what does the padding mean and lose important information.

Full training/dev set:

- After training the models with 5k training examples and 1k examples for the dev set. I decided to train the models with 21147 training set examples and 2350 dev set examples (I split the training/dev set according to tutorial 6). I trained the same models (vanilla RNN, LSTM, GRU), with the same hyperparameters above (with weight decay). The results were like this:

Model	Dev Accuracy	Improvement
RNN	10.17%	-0.43%
LSTM	69.36%	+15.96%
GRU	99.91%	+46.71%

- Accuracy of the vanilla RNN did not change when the data size increased. It still randomly classified the numbers (10% for 10 classes)
- LSTM's accuracy improved (from 53.40% to 89.74%). This indicates that LSTM benefits from using more data.
- GRU achieved near perfect accuracy. This might be happened because GRU might learned to detect "Passcode: " and focused only on the number.
- The near perfect accuracy suggests that GRU is the best model for this task.

Additional on GRU's performance

- I wanted to investigate and play with GRU's accuracy, added various hyperparameters like dropout with various hyperparameters, increased weight decay.
- One of two things happened. It was either GRU's achieved high accuracies (85%-99%) and LSTMS accuracy dropped significantly (dropped nearly to 10 %) or both GRU and LSTM achieved worse accuracies (both achieved nearly 10%). This strongly indicates that GRU is the most suitable model for the task.

Conclusion:

Data Size: I understood how important is the data size one more time. Since both LSTM and GRU improved their accuracies with more data.

Architecture: LSTM and GRU are better for tasks that require capturing long range dependencies. Gating mechanisms helped them. Vanilla RNNs suffer from vanishing gradient problem and doesn't learn anything, randomly classifies the given text.
